

4ms Pingable Envelope Generator

Eurorack Module User Manual v2012-12-20

The Pingable Envelope Generator (PEG) from 4ms Company is a dual envelope generator whose envelope lengths are set by the time between clock pulses or “pings”. The PEG has full CV control of envelope shape, skew, and ping (clock) division/multiplication, as well as a plethora of triggering and cycling options (AD, AR, quantization, cycle, cycle toggle), and a tap tempo button for each channel.

This manual covers firmware version 4 (four gold bars painted on the chips, and four flashes when entering System Mode)

DOWNLOAD MOST RECENT MANUAL AT:
<http://4mspedals.com/peg.php>

Features

- Basics:
 - Dual “pingable” envelope generator – total envelope time is set by time between pulses (“ping”)
 - Tap tempo button or external clock/triggers sets the ping time
 - Two taps sets the tempo. If a third tap is given close to the tempo to the first two taps, the two timing periods will be averaged
 - Envelope time is a multiple or division of the ping clock (from /8 to x8) set by Ping Div/Mult knob and CV
 - Curve knob and CV control the shape of the output envelope. Various combinations of exponential, linear, logarithmic, and interpolated curves, separately for rise and fall portions
 - Skew knob and CV control the ratio between rise and fall times without changing total envelope time.
 - Fastest rise time=10 μ s, fastest fall time=100 μ s. Slowest rise/fall time=15 min (30 min total)
 - Envelope is triggered by Quantized trigger jack, Asynchronous trigger jack, and/or Cycle mode
- **Outputs and scaling/shifting:**
 - Scale knob is an attenuating inverter for main envelope output
 - Maximum 0V to +10V non-inverted
 - Minimum -10V to 0V inverted
 - Bi-polar button centers main envelope output around 0V (-5V to +5V output)
 - “+5V ENV” jack is a non-scaling output that always produces a 0V to +5V envelope
 - “OR” jack outputs an analog OR mix of the two channels' scaled envelope curves
- **Gate/Trigger outputs:**
 - End-of-Rise (EOR) gate output goes high when envelope finishes a rise portion, and goes low when envelope begins a rise portion. Optional trigger mode
 - End-of-Fall (EOF) gate output goes high when envelope finishes a fall portion, and goes low when envelope begins a fall portion. Optional trigger mode
 - Half-R (Half-Rise) gate outputs 90-degree phase shifted gates that go high when 50% of the **time** of the rise portion has elapsed, and goes low after 50% of the **time** of the fall portion (this is different than a voltage comparator-based design). Optional trigger mode
 - Tap Clock Output: (enabled in System Edit Mode) dedicated Tap Tempo clock output (gate or trigger)
- **Triggering/cycling:**
 - Cycle button for each channel makes envelope self-cycle (LFO mode). Button lights up when on
 - “T” jack toggles the state of both channels' Cycle buttons while a gate is applied
 - “QNT” jack for each channel triggers an envelope to start at the next quantized beat, with respect to the divided/multiplied ping clock. Holding a gate high on this jack causes the envelope to repeat.
 - “Async” jack for each channel causes an envelope to output immediately (asynchronously). Holding a gate high results in an AR envelope (rise-sustain-fall). A trigger on Async jack enters Async mode, where the envelope is no longer phase-locked to the ping clock. A trigger on QNT exits Async mode and enters Sync mode.
- **CV input jacks:**
 - CV control of each channel's Ping Div/Mult, Skew, and Curve using the CV jacks.
 - Respective knobs set the center offset for the applied CV
 - CV of 0-10V will modulate the parameter's full range – however, a 0-5V CV will modulate the parameter within a useful range.
- **System Mode:**
 - Special mode to change advanced parameters
 - Re-assign the Half-Rise jack to EOR (and vice-versa)
 - Re-assign the EOF jack to Tap Tempo Clock output
 - Select Gate or Trigger output from EOR/EOF/Half-R jacks
 - Require a continuous external ping clock (unit will not free-run if external ping clock stops)
 - Enable/disable skew limiting that keeps fastest rise/fall times at 6ms

Dimensions

- 20 HP Eurorack format module
- 1.6” (40mm) deep

Power consumption

+12V rail:

60mA max with 5V Source jumper selecting external 5V
105mA max with 5V Source jumper selecting internal 5V

+5V rail:

40mA max with 5V Source jumper selecting external 5V
not used with 5V Source jumper selecting internal 5V

-12V rail:

35mA max

Your first P.E.G. Patch: a Basic Walkthrough

Step 1: Prepare the PEG

- Unplug all cables from the PEG, turn the Div/Mult, Skew, and Curve knobs to center (12 o'clock), turn Scale all the way up, and make sure the Cycle and Bi-polar are off (not lit up). Plug the "ENV" jack on the red channel into something you want to modulate — perhaps a filter, or the pitch of an oscillator.

Step 2: Set your Ping time

Before the PEG can generate an envelope, you need to supply a Ping time. The Ping time is the basic reference that determines the timing of the envelope.

- Tap the red channel Ping button two or three times, about a second between taps. It's easier to see what's going on with a slow envelope. The white Ping button should be flashing at the tempo you tapped. If you gave a third tap, the time between the taps will be averaged (unless the third tap occurs more than 50% different than the timing period of the first two taps)
- You also could run an external clock into the red Ping jack (when a gate is received on the Ping jack, the internal tap tempo clock is stopped).

Step 3: Provide a trigger source

Like any envelope module, the PEG will produce an envelope when it receives a trigger. Also, like many envelope modules, it can be set to self-trigger so that it'll cycle without any external trigger.

- Press the red channel Cycle button (it will light up green). Notice the white LED above the ENV jack starts flashing. The envelope is now running freely, in time with the ping clock. Adjust the other module(s) you are running the PEG into so you can hear the modulation.
- You also could turn Cycle off and run a manual trigger into the QNT or Async jack (e.g. try the Gate output from a Pressure Points, or perhaps a slow clock output from an RCD/SCM)

Step 4: Adjust your output level

- Adjust the Scale knob and/or play with the Bi-polar button to get a good voltage range that works well with whatever you're modulating with the PEG.

That's the basic PEG patch: Ping, Trigger, and Output. Now we can play with the parameters of the envelope.

Step 5: Set up your Division/Multiplication amount

- Turn the Ping Div/Mult knob to various settings and watch the Ping button flash faster and slower. Notice how the tempo doesn't change gradually, but instead jumps from speed to speed. This is because each speed is an integer multiple or division of the original tempo (e.g. three times as fast, or half as slow). You also can modulate this parameter with the Div CV jack at the bottom.

Step 6: Adjust Skew and Curve

- Fiddle with the Skew and Curve knobs to get an envelope shape you like. Notice the curve shapes in the center section of the knob are all symmetrical (same rise and fall shape), while the shapes at the start and end of the knob's range are asymmetrical (different curves for rise and fall). Of course, you can modulate these parameters with the CV jacks at the bottom.

Step 7: Play with it! Try triggering the blue channel with the red channel

- Now plug the red EOF (end-of-fall) jack into the blue Ping jack. Turn the blue channel Cycle button On. Run the blue channel "ENV" jack output to modulate something else. Set Scale and Bi-polar as desired.

Step 8: Modulate the blue channel with the red channel

- Make sure the blue Ping Div/Mult knob is set to "=", and patch the red "+5V ENV" jack into the blue channel's Div CV jack. Set the red channel Div/Mult knob to something slow. The blue channel should speed up/slow down in time with the red channel's envelope.

Keep going, play with the "T" jack, try clocking both channels the same and hitting different triggers into the QNT jacks... play with off-time triggers into the Async jack while the channel is in Cycle mode... modulate each channel with the other, or themselves... etc etc! Have fun!

Ping and Tap Tempo

"Ping" is the core of the PEG: every aspect of the envelope relates back to the timing established by the ping time. There are two ways to set the ping time:

- 1. Tap tempo button** — tap the white "Ping" button at least twice to set the timing.
 - **It's easiest to tap a tempo with Ping Div/Mult set to "="**. This is because the tap tempo clock can be divided/multiplied just like the external Ping clock. For example, if you tap a tempo with the Ping Div/Mult knob set to "x4", the Ping light will flash four times as fast as you tapped.
 - **Three taps will average**. Two taps set the ping timing period. If you give a third tap, it will be averaged with the first two taps, unless the timing period set by the third tap is widely different than the first two taps (specifically, it must be more than half, and less than twice the timing period set by the first two taps).
 - **When a gate is received on the Ping jack, the tap tempo clock is disabled**. Try tapping a fast tempo while you have a slow clock going into the Ping jack — the fast tempo will take effect immediately, but will revert back to the slow tempo when a gate is received
 - **Hold the Ping button down for 2 seconds to clear the tempo**. The light will go off and the envelope will stop. You also can clear an externally generated ping if the external unit has stopped sending pulses. If you hold it down for too long, all the lights will flash rapidly and you'll enter System Mode. Don't worry, just release and hold Ping down again for 2-3 seconds and it will go back to normal mode.
- 2. External Clock** — plug a clock or manual trigger module into the Ping jack.
 - **Only the timing between the last two pulses is used** to set the ping clock timing (no averaging). Therefore you can plug in a manual trigger/gate module and just tap in two pulses: the ping clock will continue to run at that tempo even though you're not providing any more trigger pulses. *Note: in System Mode, you can disable this free-running feature (thus, giving the PEG two external pulses will output just one envelope and then stop)* See the System Mode section.
 - **The Ping jack has no roll-off, but the main chip can process incoming clocks up to about 10kHz**. However it can only output cleanly up to about 1kHz (depending on your requirements for "cleanly"). So you can divide an 8kHz clock down to a 1.0kHz triangle wave (/8), moderately cleanly. When outputting frequencies higher than 1kHz, the output will be noisy and glitchy, but still responsive to the input frequency. Below the 1kHz threshold, the PEG can be used as a rudimentary harmonizer (e.g. sub-octave generator). See Audio Harmonizer patch.

The maximum time of either envelope curve (rise or fall) is about 15 minutes, total envelope time is 30 minutes.

Ping Divider/Multiplier

Once a ping time has been established, you can then divide or multiply it from 1/8th the speed to 8 times the speed, in whole number increments. The resulting clock is called the "Divided/Multiplied Ping Clock", or just "Ping Clock" for short.

- The Ping button flashes to the rate of the Divided/Multiplied Ping Clock
- The Ping Div/Mult knob sets the amount of multiplication or division of the incoming ping time, along with any CV that's applied to the Div jack (the knob sets the offset for the CV)
- Changing the Div/Mult amount in the while an envelope is running will immediately change the slope, and the slope will continue to track the Div/Mult amount as long as it keeps changing. If no change to the Div/Mult (or skew) is made after a practically imperceptible duration of time (about 50ms), then the envelope will re-sync to the ping clock based on the new Div/Mult amount. See Figures 1a and 1b
 - The except to the re-syncing behavior is that in Async mode, the envelope never re-syncs to the ping clock. See *Async vs. Sync* section, and Figure 2.
- Re-syncing transitions are slew-limited to prevent popping when running into a fast-responding VCA

Figure 1a: Changing Div/Mult gradually (slow knob movement) Slope of envelope tracks the Div/Mult amount until the knob stops turning (about half-way across the figure), at which point it re-syncs to the ping clock.

Figure 2: Changing Div/Mult in Async mode. Notice the envelopes **do not** land on the Ping clock (envelope is not synced to the ping clock). Also notice smooth transitions between speeds

Figure 1b: Changing Div/Mult with a sharp jump from x3 to "=" Notice the envelope didn't touch bottom in order to stay in sync with the ping clock.

Triggering/Cycling the Envelope

- QNT jack (Quantized)** — Apply a trigger/gate to this jack to cause an envelope to start **on the next ping clock**. The PEG will wait for the next divided/multiplied ping clock and then start the envelope. Holding a gate high on this jack causes the envelope to repeat. See *Figure 3a*. The envelope will complete at least one entire cycle. If a second QNT pulse is received while the envelope is running, a second envelope will be generated. If the channel is in Async mode, triggering QNT goes back to sync mode.
 - Re-phasing with QNT:** If Div/Mult is set to $/n$ (dividing), and Cycle button is on, then hitting a trigger into QNT will re-start (re-phase) the envelope on the next incoming ping clock. This can be useful for multi-phase outputs (e.g. Quadrature patch). If you want the envelope to run freely without re-phasing, just use one or the other (but not both QNT and Cycle), or don't divide the ping. See *Figures 3b and 3c*.
- Async jack (Asynchronous)** — Apply a trigger/gate to this jack to causes the channel to enter Async mode. An envelope will start immediately. Holding a gate high will cause the envelope to sustain, and then start the fall curve once the gate is released (A-S-R envelope). In Async mode, the envelope does not sync to the ping clock. However, the envelope length is still determined by the ping clock. See *Async vs. Sync section*. See *Figure 4*, also *Figure 2*.
- Cycle Button** — Press the button to toggle Cycle mode on/off. When this button is lit up, the envelope will keep running without needing any external triggers. When the button is turned off, the envelope will finish its cycle, and then stop when it "hits bottom".
 - In Sync mode ("normal" mode), turning Cycle on starts outputting an envelope from a point such that the envelope will end on the next expected ping clock (think of it as if the envelope has always been running in sync to the ping clock, and turning on Cycle un-mutes it). See *Figure 5*.
 - In Async mode, the envelope will start from 0.
- "T" jack (Cycle Toggle)** — When a gate is applied to this jack, both channel's Cycle buttons will toggle state (on->off and off->on). When the gate is released they will revert to their previous state. The "T" jack is useful for toggling between the two channels: set one channel in Cycle mode and the other channel to non-cycling, and take the output from the OR jack (see Outputs section below). The "T" jack is also useful for turning both channels on/off at the same time.

Figure 3a: Quantized QNT trigger
Applying a QNT trigger causes an envelope to output at the next ping clock (ping clock not shown in figure). Holding a gate high causes the envelope to repeat.

Figure 3b: QNT trigger with Cycle on and Div/Mult at /4
Bottom trace is ping clock. On the next ping clock after applying a QNT trigger, the envelope resets.

Figure 3c: QNT trigger used to re-phase
Blue channel (top) and Red channel (bottom) both set to $/4$, pinged by same clock. Blue is re-phased twice with QNT trigger. Envelopes start in-phase, then Blue lags by 90° , then they are re-phased back together.

Figure 5: Asynchronous trigger
Trigger causes an envelope to start/re-start immediately. Holding a high gate causes a sustain period followed by a fall period when the gate goes low (ASR envelope)

Figure 4: Pressing Cycle button in Sync mode
When Cycle is turned on, envelope starts outputting instantly, from a point in its cycle such that it's in sync with the divided ping clock. (Blue trace indicates cycle button ON or OFF)

Skew

Skew is the ratio between the rise and fall times (slopes). Unlike most envelope generators, in the PEG the total envelope length is held constant when the skew is changed, thus allowing you to change between ramp-up, ramp-down, triangle, and everything in-between, without altering the timing. See *Figure 6*.

If Skew is changed while an envelope is running, the curve will update immediately. Some funky outputs can result from this. See *Figure 7*.

Skew Limiting: Normally the fastest rise time is 10uS, fastest fall time is 200uS. This can sound great into an LPG, LPF, or modulating all sorts of things, but it's fast enough to cause an audible click into some highly responsive VCAs (such as the 4ms VCA Matrix). Obviously, if you back the Skew knob off from the max/minimum settings the skew will be reduced enough to avoid popping. However, if you are modulating skew with CV it can require some careful attenuation to prevent popping. A shortcut solution is built into the PEG's System Mode. When Skew Limiting is enabled, the fastest rise or fall time allowable will be 6ms, which is slow enough to prevent VCA popping. See the *System Mode* section for the procedure of how to set the Skew Limiting parameter (it's the white ENV light).

Figure 6: Skew examples. Skew knob was turned up a little bit in between each envelope.

Figure 7: Funky envelopes made by twiddling the skew parameter while envelope is running

Curve

The envelope shapes available in the PEG are formed by combinations of exponential, linear, and logarithmic waveforms. In between each fully expo/lin/log waveform, there are three interpolated waveforms formed from weighted combinations of each (e.g. 25% log, 75% linear). The waveforms can be symmetrical (e.g. linear rise & linear fall), or asymmetrical (e.g. exp rise & log fall). See *Figures 8a-8d*.

The curve is selected from one of 17 using the Curve knob and CV jack (the knob sets the offset for any applied CV). Look closely at the artwork around the Curve knob on your PEG to see how the curves are arranged. Asymmetrical curves are at the extremes, and symmetrical curves are in the center.

As you turn the knob from 0 to max (clockwise), the curves change like this:

- First 4 curves are asymmetrical with exponential attacks and different decays (log->expo) *Figure 8a*
- Next 4 curves are symmetrical, ranging from exponential to linear in 4 interpolated steps. *Figure 8b*
- Middle Curve is linear (triangle wave)
- Next 4 curves are symmetrical, ranging from linear to logarithmic in 4 interpolated steps. *Figure 8c*
- Last 4 curves are asymmetrical with logarithmic attacks and varying decays (log->expo) *Figure 8d*

Once a rise or fall segment has begun, the shape will not change until the segment ends. However, applying a pulse on the QNT jack or turning the cycle button on will force an immediate update of the curve shape.

Figure 8a: Curves 1-5
Asymmetrical curves with expo attacks

Figure 8b: Curves 5-9
Symmetrical curves (expo to linear)

Figure 8c: Curves 9-13
Symmetrical curves (linear to log)

Figure 8d: Curves 13-17
Asymmetrical curves with log attacks

Envelope Outputs (Main ENV, +5V ENV, OR)

Each side of the PEG has two outputs: a scaled output labeled "ENV" and an unscaled output labeled "+5V ENV". Additionally, there is a shared output that's the arithmetic "OR" of the scaled outputs.

- The Scale knob and Bi-polar button only effect the ENV output jack:
 - With Bi-polar off: If the scale knob is right of center, the output will be positive-only, from 0V to a maximum of +10V. Left of center, the envelope inverts and is negative-only, from 0V to a minimum of -10V.
 - With Bi-polar on: Scale knob right of center, the output will rise from negative to positive, then fall back to negative voltage (maximum range -5V to +5V). Scale knob left of center, the output starts positive and "rises" to negative voltage, then "falls" back to positive voltage.
 - In any setting, Scale knob in the center will produce no output.
 - The Bi-Polar button is a level-shifter before the scale/inverter. The amount of level-shifting is controlled by a trim pot on the back of the module. Factory setting is a shift of -5V (thus 0V to +10V becomes -5V to +5V). One common use would be to set this to about -10V of level shift, so that the output when Scale is inverting would be positive voltages, but with an inverted waveshape. In this way, the +5V ENV jack and main ENV jacks will produce inverted copies of the same waveshape, both uni-polar.
- The main output is the ENV output and its amplitude is controlled by the Scale knob and Bi-polar button
- The +5V ENV jack always outputs a waveform that goes from 0V to +5V. The scale and bi-polar controls have no effect on this. This jack is useful as an auxiliary envelope output. It's often useful to patch into the other channel's CV jack(s) to modulate parameters.
- The OR jack will output the highest voltage value from either side's ENV jack at any given moment. One way to use this is to think of the OR jack as a mix out, and use the Scale knobs as level knobs and the Bi-Polar buttons to bring down the relative level of a channel (kind of like a mute button). See Figure 9c

Figure 9a: Changing Scale (Bi-polar off)

Figure 9b: Changing Scale (Bi-polar on)

Top traces are ENV as Scale is turned from max to min. Bottom traces are +5V ENV. Grid lines are 5V/division.

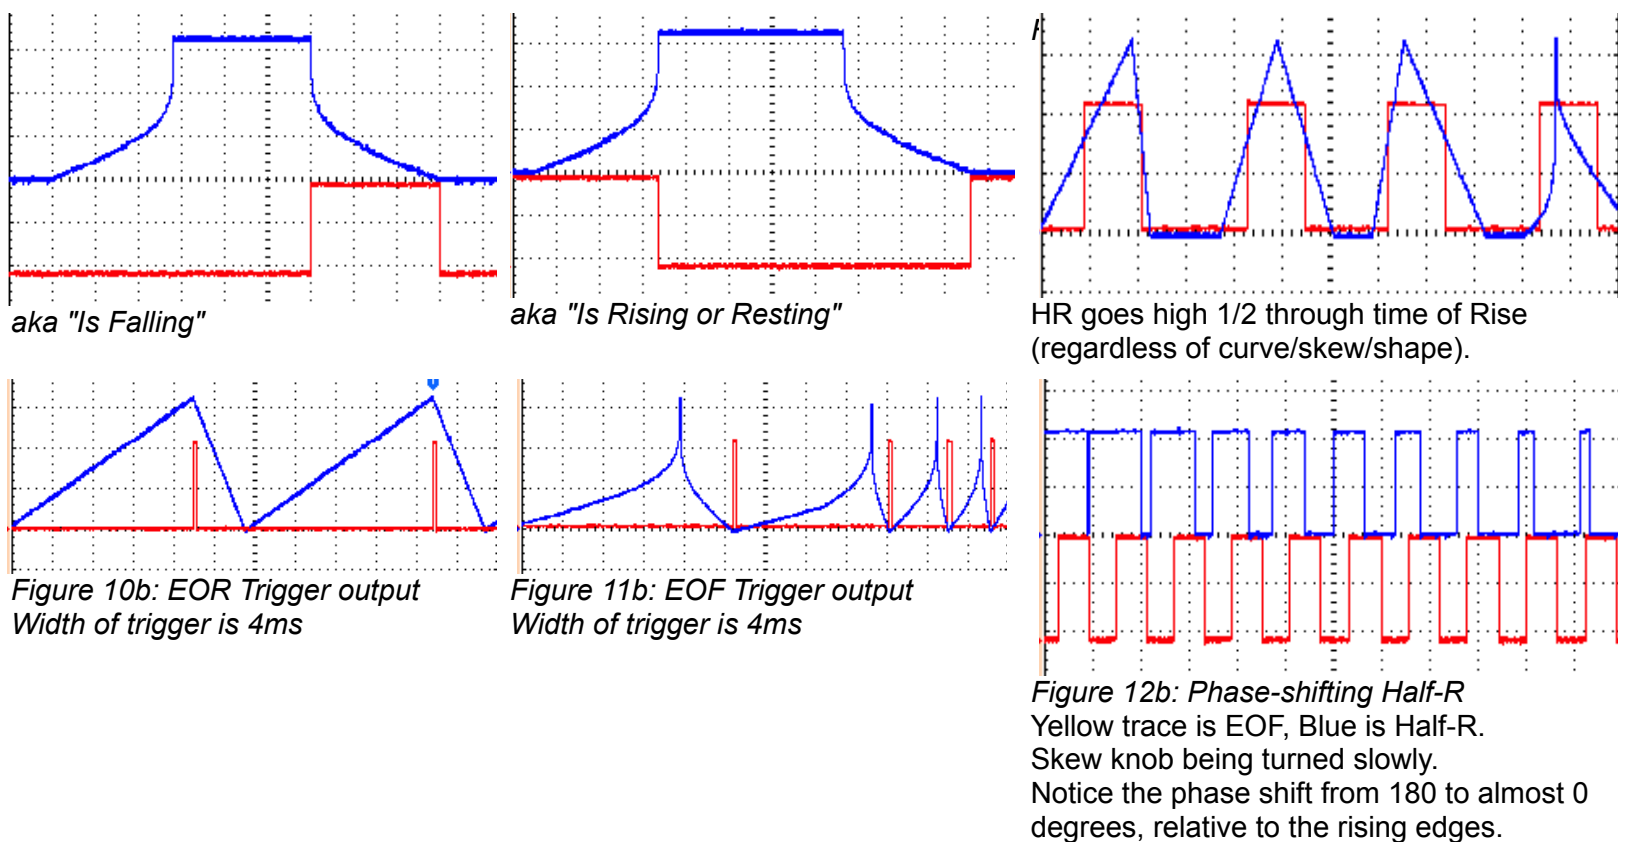

Figure 9c: OR jack vs. adding ENV outputs
Top trace is OR jack (one channel is being sped up). Bottom trace is from mixing both channels using a passive mult.

Gate Outputs (EOR/EOF/Half-Rise)

Each channel has a two gate outputs: End-of-Fall (EOF), and either End-of-Rise (EOR) or Half-Rise. System Edit Mode can be used to change the functionality of these jacks, as well as select whether each jack outputs gates or triggers.

- End-of-Rise outputs a gate that goes high when the fall segment begins, and goes low when the envelope completes. It is low during a sustain segment. The jack will stay low when the envelope is not running. Another name for this jack might be "Envelope is Falling". System Mode selects whether it outputs gates or triggers. See *Figures 10a and 10b*.
- End-of-Fall outputs a gate that goes high when the fall segment ends and goes low when a rise segment ends. It is low during a sustain segment. It will stay high when the envelope is not running. Another name for this jack might be "Envelope is Rising or Resting". System Mode selects whether it outputs gates or triggers. See *Figures 11a and 11b*.
- Half-Rise outputs a gate that goes high when 50% of the envelope's rise time has elapsed. It goes low when 50% of the fall time has elapsed. It is high during a sustain segment, and stays low when the envelope is not running. System Mode selects whether it outputs gates or triggers. See *Figure 12a*.
- Skew has a big effect on the EOR/EOF/HR jacks:
 - Skew changes the pulse width of EOF and EOR in gate mode. Turning Skew to the right (more CV) creates longer EOR gates and shorter EOF gates. To the left, we get shorter EOR gates and longer EOF gates.
 - The width of the Half-R gate is always 50% of the envelope time. Changing the Skew will change the phase of the Half-R output, but not the width. See *Figure 12b*.

Tap Tempo Clock Output

By using System Edit Mode, you can re-assign the EOF jack to output the tap tempo clock (see *System Edit Mode section for the procedure*). With this enabled, the EOF jack will always output a free-running clock that you can set by tapping in a tempo. The jack will always output a steady TTC (Tap Tempo Clock), no matter if the envelope is running or not, and regardless of the skew, div/mult, or curve settings. In System Mode you can select gate or trigger output.

This is useful for using the PEG as a master clock source.

You can use the Ping button and the EOF jack (which is really TTC) as a separate "module", independent of whatever's happening with the envelope. That is, the TTC will run steadily no matter how you ping the channel, or set Div/Mult, or (re-)trigger, Cycle, Skew, etc... The only thing that will change the TTC is physically pressing the Ping button.

One common use for this is to simply patch EOF/TTC into the other channel's Ping jack. Now the channels are synced to your tap tempo! Or patch the EOF/TTC into a clock divider/multiplier, patching one of the clock outputs back to the same channel's Ping jack. The remaining clock outputs can be used to keep your other modules in sync with the Tap Tempo clock on the PEG. You can change the Div/Mult settings on the PEG, or start and stop the PEG's envelope, and your Tap Tempo Clock will keep running steady.

Async vs. Sync Mode

There are two main modes the PEG runs in: Sync mode and Async mode. The two modes effect the way the envelope is sync'ed (or not) to the Ping clock. The difference between the modes is easier to see when the Cycle button is on.

How to change between modes:

When the PEG turns on, it starts in Sync mode.

- To enter Sync Mode: Give a trigger/gate into the QNT jack
- To enter Async Mode: Give a trigger/gate into the Async jack
- *Tip:* If you don't have an external trigger module handy, an quick (and dirty) way to switch modes is to momentarily plug QNT or Async into any jack that has a light on or flashing (ENV, +5V ENV, EOR, EOF, Half-R)

Differences between modes: (much easier to see with Cycle button on)

- **Sync Mode:** This is the "normal" PEG mode. The envelope is locked to the Ping clock: it always starts and stops on the ping clock unless you are rapidly changing Skew or Div/Mult (in which case the PEG will snap back to sync when about 50ms have passed since any modulation change). See *Figures 1a and 1b in the Ping Divider/Multiplier section*
- **Async Mode:** In Async mode, the envelope will try to start on the same point in time relative to the ping clock, but this point of time (called the "async reset point") can change. With Sync mode, this point in time is the (divided/multiplied) ping clock itself – but with Async mode, this can be any arbitrary point in time in the ping's cycle. This "async reset point" can either be set intentionally by hitting a trigger on the Async jack, or it can just "float into place" if you modulate parameters which change the envelope's landing point. An Async envelope can be 0° to 360° out of phase with the ping clock, which is useful for phase modulation.
 - Using Async triggers to change the "async reset point": Try this patch: supply a Ping clock that's about 1 pulse per second. Use the same clock to make a sound with some other module, using this as a metronome/reference. For simplicity, turn Div/mult to "=" and Skew to about a sharp rise (maybe 90%). Turn cycle mode on. Hit a trigger into Async about half a second after a ping. The envelope will restart when it receives the trigger and will continue to cycle, always starting half a second after each ping. This is your "async reset point": half a second after the ping. Hit another trigger just a moment before the ping. Now the the envelope will always be starting just a moment before each metronome pulse. Keep playing with it till it makes sense, this is an advanced but very useful technique. See *Figure 13a*
 - Using skew/div modulations to change the "async reset point": Patch the example above. Try turning Skew back and forth, as well as Div/Mult. Smooth, huh? Stop turning the knobs and notice how it's now starting at a different point relative to the metronome. The "reset point" has changed to accommodate your knob wigglings. If you were in sync mode, it would have snapped back to starting on the ping clock. But in Async mode, it can start anywhere. See *Figure 2 and Figure 13b*.

Figure 13a: Async mode (re-triggering)
Envelope starts at the same point on the ping clock: for the first 3 clocks it's approximately the falling edge of the ping. About half-way through the figure, another async trigger is given and the reset point becomes a little bit before the rising edge.

Figure 13b Async mode (Turning Skew knob in cycle mode)
Since the envelope is not locked to any point on the ping clock, it may lengthen or shorten to accommodate the user changing the Skew parameter.

Beyond Mere Envelopes... Advanced PEG Patching

Hopefully after reading this far into the manual and playing with your PEG, you have a clear understanding of how to make a variety of timing-dependent envelopes. The following patches illustrate how the PEG's large assortment of inputs and output types can be used for a variety of purposes besides envelopes.

Clocking both channels with the same clock:

This is a common requirement of many patches. Here's some ideas:

- Mult an external clock and run it into both Pings.
- Enable Tap Tempo Clock Output in System Edit mode and run EOF to the other channel's Ping.
- Run multiple outputs from a clock divider/multiplier, and then mult/divide on the PEG to make them the same tempo
- If your patch doesn't modulate Div/Mult and one channel always will be running, then you can run EOF into the other channel's Ping.

Complex pattern generator

Use the PEG's quantization features to create complicated repeating beat patterns. It's helpful to have a "metronome" or "kick" in the background at the steady master clock rate (or slow division of the master clock)

- Run a Shuffling Clock Multiplier x8 output (or RCD /1 out) into Ping. Run another SCM output, say S5 or RCD /3, into QNT. Cycle Off. Div/Mult to "=". Run the ENV output to open a filter (try a 100% Skew, triangle Curve). If the beat pattern isn't groovy, use a different clock output into QNT (use the SCM's slip/shuffle!), and adjust Div/Mult.
- To increase complexity, run EOF into the other channel's Ping. Turn that channel's Cycle on or run a different clock into QNT. Play with Div/Mult. Use the OR out, or run its ENV out to modulate another sound, or perhaps a second aspect of the same sound. If you can, play with the pulse width of the module feeding QNT jacks (the SCM Breakout has a PW knob and jack, as do many VCOs and LFOs). Longer PW means more repeated notes.
- Another technique: Patch Tap Tempo Clock output to a clock divider/multiplier module (e.g. SCM). Run a fast output to PING (e.g. x6). Run a slow output to QNT (e.g. x2). Turn Cycle off. Adjust Div/Mult (e.g. "=") and try different outputs from the clock divider/multiplier module until you get interesting rhythmic patterns.

"Ratcheted" quantized beats

Control the repeat rate of each note in a sequenced bassline.

Clock a sequencer and run the same clock into Ping. Presumably one CV output from the sequencer is controlling the pitch of your "bassline". Patch a different CV output of the sequencer into Div CV. Turn Cycle on (or run the sequencer's Gate output into the QNT jack). Set each step to a CV value that corresponds to the number of repeats you want for that particular step. For example, suppose you have an 8-step sequence and you want notes to be played once for every step until the last note, which you want to be repeated 8 times and played 8 times as fast... set the sequencer steps 1-7 to 0V output, and step 8 to 5V.

If you want to control the number of times the note repeats (e.g. 8 times as fast, but only hit 4 times), you can use a sequencer with variable pulse width for its gate output (patched into the QNT jack) or another module to change the pulse width (e.g. Seq Gate->SCM In and SCM x1 -> PEG QNT, playing with SCM's PW knob)

Alternating Skew (or div/mult)

Enable Tap Tempo Clock output. Unplug any external ping. Tap a slow tempo with the Ping button. Turn Skew to 0. Turn Div/Mult to x8. Turn Cycle on. Patch EOF to Skew CV. You will get four pulses of ramp-up saw followed by four pulses of ramp-down saw. Try patching into Div CV or Curve CV instead of Skew. Try running EOF through an attenuator before back into the PEG.

Self-oscillation (self-patched)

Very chaotic interesting noises. Needs a human to fine-tune the settings. Spend some time on this one!

Patch EOF to Ping. Patch ENV output to your audio mixer. Set Div/Mult to between = and x2 (adjust this very slowly throughout the patch). Cycle On. Scale will be your output volume. Skew and Curve effect the "timbre" (heh). Give PING a few taps to get it started.

More advanced: Do the basic patch to both channels, with both ENV outputs going to an audio mixer (or just listen to the OR output). Now patch Half-Rise into the "T" jack. Play with Cycle button settings. Keep patching each channel into itself and/or the other. Try running one channel's output to control a filter, the other controls a VCO running into the filter.

Video scroll sync

Make sure you are in Sync mode (run a trig->QNT). Use a VCA or logic gate to AND the video Field Sync with a scrolling audio-rate oscillator. Patch that into PING. You automatically get an LFO that's transposed to the visual scrolling speed of the pattern (*thanks to Lars*).

Variation: Run AND'd sync into the QNT trig of the PEG. Then run a different audio-rate oscillator into the PING jack. Cycle button Off. It will still track the scrolling speed of the first pattern, but the second oscillator controls scrolling within the scrolling.

Audio Harmonizer

Sub-octave and harmonic series from an audio input

Run an oscillator into Ping input. Cycle On. Set your frequency shift amount with the Div/Mult (e.g. x2 will be an octave up, x3 will be an octave plus a fifth, /8 will be three octaves down, etc...). Audio output from the ENV jack. Scale sets your volume. Skew and Curve set your waveshape/timbre. Keying Async will mute the signal. Turning Cycle off and keying QNT will gate the signal.

Do this on both channels and use the T jack to toggle between harmonics, taking the output from the OR jack. Unplug one channel's Ping to let it slowly drift, creating phaser swooshing sounds.

Run into a LPF with roll-off at 10kHz for a less harsh sound!

Clockable Trigger Delay

A trigger is fed in, and after a delay (which is determined by a clock), a trigger is outputted.

Patch a trigger (e.g. from Pressure Points gate output) to the Async jack. Patch a clock into the PING jack. Set Div/Mult to /2. Set Skew to center. EOR will be your delayed trigger output (actually is a gate as wide as the clock period). Changing Skew will fine-tune the delay time as well as output gate pulse width. To get a true trigger output, enable EOR trigger mode in System Edit mode.

Keyboard Tempo Tracking

Play a keyboard and the repeat rate of the notes is defined by how fast you hit the keys

Patch a keyboard gate into PING (perhaps use the gate output of a MIDI/CV module, with a MIDI keyboard running in... or a CV/Gate keyboard, or a Pressure Points. Patch the keyboard CV to a 1V/oct VCO. Run the VCO through a LPG or VCA and use PEG's ENV out to open the LPG or VCA. Turn Cycle on. Find a nice sounding Skew/Curve combination. The tempo that you hit the keyboard notes will determine the tempo— hit a key twice and it'll keep repeating at that rate. Play faster and your repeat rate increases. To keep patching, run another CV (perhaps CC controller CV from the MIDI module, or a second row on the PP) to control Div/Mult or Skew and Curve.

Phase Shifting

Variable phase shift – two sets of events have variable amount of stagger.

Clock both channels with the same clock (see first example patch idea). Cycle on (both channels). Use both main envelope outputs to make sound (open two VCAs, perhaps).

Some options for setting the amount of phase difference:

- **Manual trigger into Async jack on one channel.** For example, to set the blue channel to lag by 25% (90° phase difference), hit the trigger a quarter of the way after a red channel pulse. Any phase shift amount is possible.
- **CV Skew.** Changing the skew will change the timing that the peak of the envelope occurs. Thus, sweeping the Skew of one channel while holding the other steady will cause the envelope peak to shift in phase with respect to the other envelope's peak. This only a perceptual phase-shift.
- **Quantized phase selection.** Slow each channel down to /8. Speed your clock up if necessary. Give a trig to both channel's QNT jacks to make sure you're in Sync mode. Turn blue channel cycle off. Listen to the red channel, and at a moment *just before* you want the blue channel to come in, press the blue Cycle button on. The blue channel's phase will be quantized to one of 8 possible phases (0°, 45°, 90°, 135°, 180°, 225°, 270°, or 315°). It helps to set a sharp attack on the red channel (Skew at 100%) so you can hear the timing better. Cycle button can be turned off and back on to change phase again. Use different Div settings for different possible phase shift amounts (e.g. /7 gives 0°, 51°, 102° etc...)

Quadrature patch

1) First, you have to set up the phase difference between the two channels:

- **The easy way:** Clock both channels with the same clock (see first example patch idea) and patch the blue channel Half-R into red channel Async. Turn blue Cycle on and red Cycle off. Adjusting the Skew of the blue channel will change the amount of phase shift from 0-180° (50% skew will be 90°). *Note: Half-Rise output should be in trigger mode or you may get a trapezoidal waveform on Red.*
- **Another way, just for kicks:** Clock both channels together and set both to /4. Give both channels a QNT pulse so they are in Sync mode. Using the same technique as described in the *Quantized phase selection* patch above, hit the Cycle button at the right moment so that one channel is 90 degrees out of phase as the other. Or if you really like doing things the most complicated way possible, turn blue Skew one mark to the right of center, turn red Cycle off, wait for red envelope to finish, wait for the blue Half-R LED to go off, and immediately patch blue Half-R into red QNT. The two channels will be 90 degrees out of phase. Bonus points if you can figure out why! (hint: Skew just right of center means Half-Rise goes high just before 25% of the entire envelope has passed...)

2) Now adjust the levels:

- Turn both Scale knobs to about 10:00 (inverting), and both Bi-polar buttons on. Run the main ENV outputs into a Level Shifter (e.b. Bubblesound LvL+rm or Doepfer A-129/3) to add about 2.5V so that the inverted signals are at the same DC offset as the +5V ENV outputs. Your four phase shifted outputs will be Blue +5V ENV (0°), Red +5V ENV (90°), Blue level-shifted ENV (180°), Red level-shifted ENV (270°).

If you use this patch often and want to avoid using an external level shifter module, you can adjust the Bi-Polar trim pot as described in the Bi-Polar section above.

Jumpers

Blue channel detection jumper

Must be installed for proper operation. It may be removed temporarily if you are connecting an ISP programmer to do a firmware update. After the update, re-install the jumper, and cycle the power. The state of the jumper is only read on power-on.

5V source select jumper

Jumper on INT: 5V is created from the 12V power rail (factory setting — shown in photo)

Jumper on EXT: 5V drawn from 5V power rail.

Note: In firmware versions 1 and 2, the jumper enabled/disabled Half-Rise mode. In firmware versions 3 and later, the jumper should always be on the blue channel and Half-Rise must be enabled/disabled with System Mode

System Mode

System Mode is an advanced feature of the PEG that can be used to re-assign the functionality of jacks, and change operation in general. It is only present in firmware version 3 and later (v3 has three gold bars painted on the chips, v4 has four gold bars). Each channel (red/blue) has an independent system mode, that is, changes made on one channel will have no effect on the other channel.

To enter System Mode:

- Hold the PING button down for 5 seconds (after 2 seconds the tap clock will clear, keep holding it down!)
All the lights except Bi-Polar will flash:
 - Version 4: lights will flash 4 times
 - Version 3: lights will flash rapidly 5 times
- Release the PING button.
- Tap the PING button a few times and notice how one light comes on at a time. This indicates which feature you are editing. Keep tapping PING to see that you can edit EOR/Half-R, EOF, ENV, or PING. (*Note: "ENV" refers to the white LED next to the Bi-Polar button and above the ENV jack*)
- When a feature is selected, pressing the Cycle button will switch between settings:
Legend:
 - OFF = Cycle light off*
 - DIM FLICKER = Cycle light blinking slowly and dimly (not an option for all parameters)*
 - ON = Cycle light on*
 - BRIGHT BLINK = Cycle light blinking quickly and brightly (not an option for all parameters)*
- **EOR/Half-R:**
 - *OFF:* jack will output End-of-Rise Gates (*factory setting for Red channel*)
 - *DIM FLICKER:* jack will output End-of-Rise Triggers
 - *ON:* jack will output Half-Rise Gates (*factory setting for Blue channel*)
 - *BRIGHT BLINK:* jack will output Half-Rise Triggers
- **EOF:**
 - *OFF:* jack will output End-of-Fall Gates (*factory setting*)
 - *DIM FLICKER:* jack will output End-of-Fall triggers
 - *ON:* jack will output the Tap Tempo Clock (TTC) Gates. See section on Tap Tempo Clock Output
 - *BRIGHT BLINK:* jack will output Tap Tempo Clock (TTC) triggers.
- **ENV:**
 - *OFF:* No skew limiting (fastest rise time 10us, fastest fall 200us) (*factory setting*)
 - *ON:* Skew limiting enabled (fastest rise or fall time 6.5ms) *See Skew section in manual*
- **PING:**
 - *OFF:* Ping clock keeps running regardless of whether the external clock has stopped (*factory setting*)
 - *ON:* Ping clock will stop if the external clock stops. If Tap Tempo Clock is also enabled (gate or trigger), then the PEG will automatically start using the Tap Tempo Clock
- When you are satisfied with your new settings, press and hold PING for two seconds. All the lights will flash a few times again. Now you are back to normal operation.
- System Mode settings are saved in EEPROM memory, so they will be "remembered" after powering down.

Why would I want to change my system settings?

- **Triggers vs. Gates:**
Many modules respond differently to gates and triggers. If you are patching EOR/EOF/etc into a standard ADSR module, you can omit the sustain portion by using triggers. Or perhaps you want to use EOR as a gate to start and hold the ADSR, and EOF as a trigger to re-trigger it. Or, patching from the EOR/EOF jacks into the Async jack, a gate might give you a sustain portion, but a trigger will avoid that. Patching into a VCA or LPG, a gate will hold it open for a longer period, while a trigger will just "flash" it open for a brief instant.
- **EOF vs. Tap Tempo Clock (TTC):**
Usually you will enable this if you want to use the PEG as a master clock. Another reason might be to sync both channels together. See the Tap Tempo Clock section, as well as the patch example "Clocking both channels with the same clock"
- **Skew Limiting:** *See also Skew section*
You may want to enable this if you are hearing lots of popping when running into a fast-responding VCA and/or modulating the Skew to its extremes. Note that the exponential and log curves can cause clicking, as they are (by their nature) fast-changing envelope shapes. These shapes are typically used with a linear VCA, as exponential VCAs often want to see linear curves. With slower-responding resonant modules (such as a low-pass gate), the expo/log curves and non-limited skew shapes can be especially delicious....
- **Ping keeps running vs. Ping stops when external clock is stopped**
If you are pinging the PEG with an external clock, it can be counter-intuitive to have the PEG continue running when the clock stops. Also, it can seem weird if the clock slows down substantially but the PEG keeps running at the old fast tempo for a bit. Stopping the PEG when the clock stops (or slows down, the PEG can't tell the difference until a new clock pulse is received) solves these issues. On the other hand, letting the ping clock run even if it's stopped getting pulses can be a nice feature since you could just tap two pulses into the PING jack and it will run. For an example, see the Keyboard Press Defines Tempo patch
